1 OpenWhisk Package Specification

2 Version 0.8, Working Draft 08

3 *Notational Conventions*

4 The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
5 "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
6 document are to be interpreted as described in RFC 2119.
7 The OpenWhisk specification is licensed under The Apache License, Version 2.0.

8 Introduction

9 OpenWhisk™ is an open source, distributed Serverless computing project.
10 Specifically, it is able to execute application logic (*Actions*) in response to events (*Triggers*)
11 from external sources (*Feeds*) governed by simple conditional logic (*Rules*) around the event
12 data.
13
14 It provides a programming model for registering and managing *Actions*, *Triggers* and *Rules*
15 supported by a REST-based Command Line Interface (CLI) along with tooling to support
16 packaging and catalog services.
17
18 The project includes a catalog of built-in system and utility *Actions* and *Feeds*, along with a
19 robust set of samples that demonstrate how to integrate OpenWhisk with various external service
20 providers (e.g., GitHub, Slack, etc.) along with several platform and run-time Software
21 Development Kits (SDKs).
22
23 The code for the Actions, along with any support services implementing *Feeds*, are packaged
24 according to this specification to be compatible with the OpenWhisk catalog and its tooling. It
25 also serves as a means for architects and developers to model OpenWhisk package Actions as
26 part of full, event-driven services and applications providing the necessary information for
27 artifact and data type validation along with package management operations.

28 Compatibility

29 This specification is intended to be compatible with the following specifications:
30   • *OpenWhisk API which is defined as an OpenAPI document:*
31   • https://raw.githubusercontent.com/openwhisk/openwhisk/master/core/controller/src/m
32   ain/resources/whiskswagger.json
33   • *OpenAPI Specification when defining REST APIs and parameters:*
34   • https://github.com/OAI/OpenAPI-Specification/blob/master/versions/2.0.md

35

36 Revision History

Version	Date	Notes
0.8.1	2016-11-03	Initial public point draft, Working Draft 01
0.8.2	2016-12-12	Working Draft 02, Add. Use cases, examples
0.8.3	2017-02-02	Working Draft 03, Add use cases, examples, $ notation
0.8.4	2017-04-18	Working Draft 04, Support JSON parameter type; Clarify use of Parameter single-line grammar and inferred types. Add support for API Gateway mappings. Add support for Web Actions
0.8.5	2017-04-21	Add support for "dependencies", that is allow automatic deployment of other OpenWhisk packages (from GitHub) that the current package declares as a dependency.
0.8.6	2017-07-25	Clarified requirements for $ dollar notation. Updated conceptual Manifest/Deployment File processing images.
0.8.7	2017-08-24	Added explicit Application entity and grammar. Added API listing to Package entity. Cleaned up pseudo-grammar which contained various uses of credentials in places not intended. Fixed Polygon Tracking example (indentation incorrect).
0.8.8	2017-08-29	Created a simplified API entity (i.e., "api") grammar that allows multiple sets of named APIs for the same basepath. Acknowledge PHP as supported runtime (kind). Added "sequences" entity as a convenient way to declare action sequences in the manifest. Updated supported runtime values.

37

Table of Contents

Programming Model

OpenWhisk Entities

OpenWhisk uses the following entities to describe its programming model:

Action

A stateless, relatively short-running function invoked as an event handler.
Note: Typically, an Action's run time is on the order of seconds or even milliseconds, but usually well under the defaulted maximum of 5 minutes.

Trigger

The name for a class of events. Triggers represent the events (and their data) themselves without any concept of how they were generated.

Rule

A mapping from a Trigger to an Action which may contain simple conditional logic. OpenWhisk evaluates incoming events (that belong to a Trigger) and invokes the assigned Action (event handler).

Note: Rule conditional logic can be described relative to the event data and the target Action input parameters.

Note: In a pub-sub system, a trigger could be viewed as a message topic.

Event Source

An Event Source is the descriptor (edge) for an Event Producer (or provider). It describes the Event Format(s) produced, as well as any configuration and subscription capablities.

Feed

A Feed is an optional service that allows control operations (e.g., configure, start, stop, pause, resume, etc.) and configuration of Events coming from an Event Source.

Note: The terms Feed and Trigger are often used interchangeably conversationally (since they both represent a class of events); however, we make this distinction.

Package

A named, shared collection of Actions and Feeds. The goal of this specification is to describe OpenWhisk packages and their component entities and resources to enable an open-ecosystem.

Note: Not all actions must belong to packages.
Note: Designed as a first-class entity within the OpenWhisk platform to be used by tooling such as catalogs (repositories), associated package managers, installers, etc.

Package processing

This document defines two file artifacts that are used to deploy Packages to a target OpenWhisk platform; these include:

- **Package Manifest file**: Contains the Package definition along with any included Action, Trigger or Rule definitions that comprise the package. This file includes the schema of input and output data to each entity for validation purposes.
- **Deployment file**: Contains the values and bindings used configure a Package to a target OpenWhisk platform provider's environment and supply input parameter values for Packages, Actions and Triggers. This can include Namespace bindings, security and policy information.

Conceptual Package creation and publishing

The following diagram illustates how a developer would create OpenWhisk code artifacts and associate a Package Manifest file that describes them for deployment and reuse.

1. Developer *creates* and *reposits* Serverless code, including:
   - Actions (functions) and
   - Feeds for Event Sources (i.e., Event Providers)

2. Creates a *Package Manifest File* which describes the Serverless service's:
   - Repositories (source code locations)
   - Parameter schema (for Actions and Feeds)
   - Configuration and Lifecycle APIs for Feeds
   - Event Sources (and corresponding Event schema)
   - Triggers and Rules
   - Compositions of Actions
   - Annotations (tags, User Interface hints, etc.)

3. Publishes *Package Manifests* to enable Catalog features for Serverless services:
   - Automated or manual Discovery and Search
   - Graphical Display / Selection
   - Functional applicability
   - Compositional type validation

141   Conceptual tooling integration and deployment

142   The following diagram illustrates how Package manifests can be leveraged by developer tooling
143   to integrate OpenWhisk Serverless functions.

1. Developer *searches* and *discovers* OpenWhisk packages described by the *Package Manifest* in one or more Catalogs, that can:
   - Help analyze, augment and annotate application information and data.
   - Add value added functionality to a base application or workflow.

2. Imports Open *Package Manifest Files* and related code and artifacts into development tooling, including:
   - Project and Application (source code) Repositories
   - Integrated Development Environments (IDEs)
   - Cloud-based design, workflow and application workspaces.

3. Creates OpenWhisk *Deployment Files* for one or more target OpenWhisk enabled Clouds, with
   - Parameter values for desired target environment
   - Appropriate Credentials and configurations for chosen Event Sources and Feeds.

4. Deploys *Packages* (i.e., Actions, Triggers, Feeds, etc.) to OpenWhisk enabled Clouds, using,
   - *Package Manifest* and *Deployment File(s)*.

144

145   *Notes*
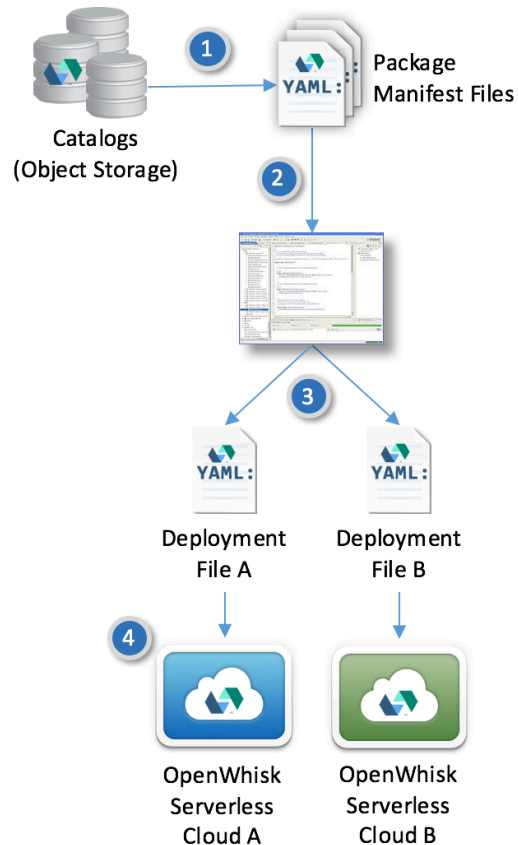

146   • Deployment Files are optional. Deployment can be fully accomplished with simply the Manifest File.

147 Conceptual representation
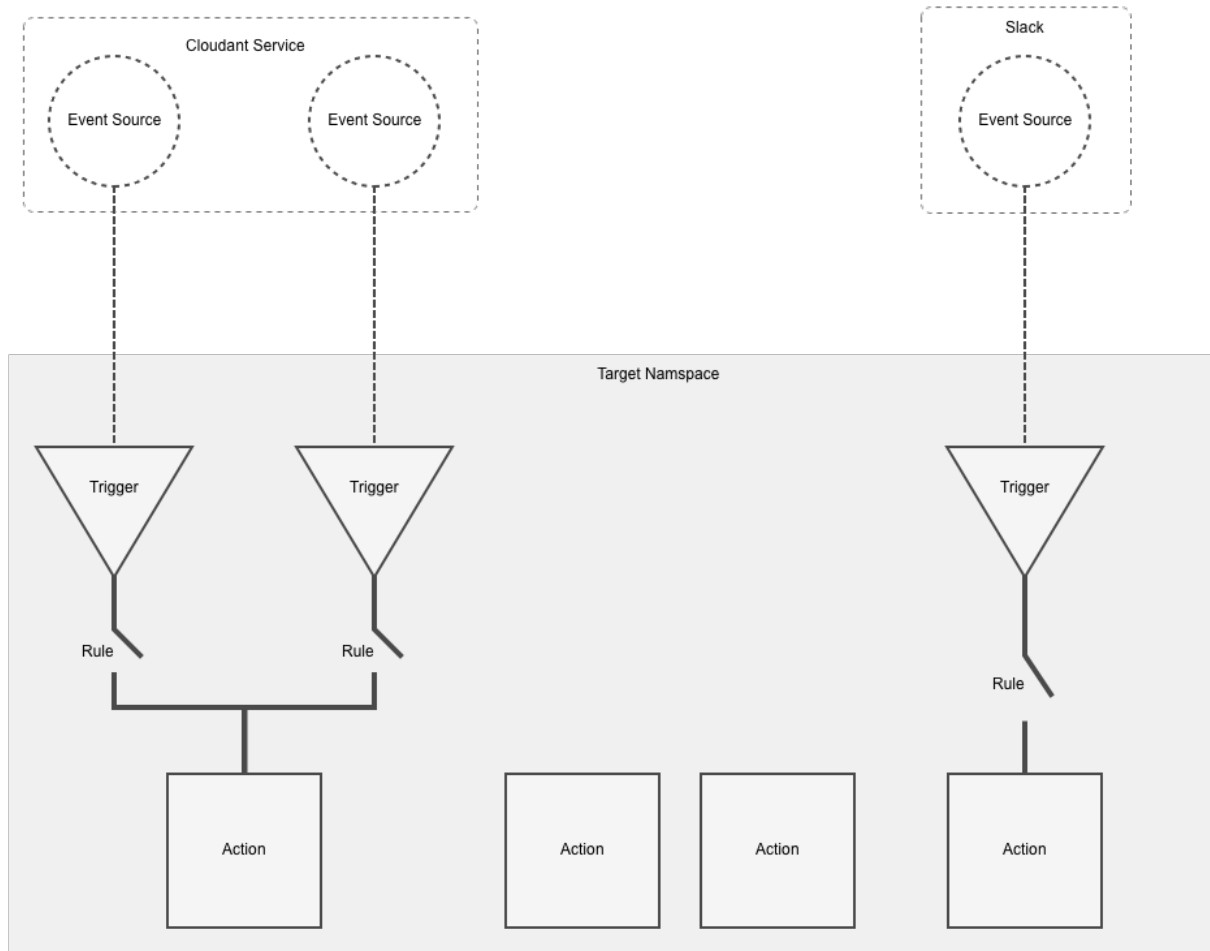

148

149 Composition

150 *Action Sequence*

151 An Action that is a sequenced composition of 2 or more existing Actions. The Action Sequence
152 can be viewed as a named pipe where OpenWhisk can automatically take the output of a first
153 Action 'A' in a declared sequence and provides it as input to the next Action 'B' in the sequence
154 and so on until the sequence completes.

155
156 *Note: This composition technique allows the reuse of existing action implementations treating*
157 *them as "building blocks" for other Actions.*

158 Namespacing

159 Every OpenWhisk entity (i.e., Actions, Feeds, Triggers), including packages, belongs in a
160 *namespace.*

161 The fully qualified name of any entity has the format:

```
162    /<namespaceName>[/<packageName>]/<entityName>
163
```

164   The namespace is typically provided at bind-time by the user deploying the package to their
165   chosen OpenWhisk platform provider.

167   *Note: The `/whisk.system` namespace is reserved for entities that are distributed with the*
168   *OpenWhisk system.*

Entity Names

170   The names of all entities, including actions, triggers, rules, packages, and namespaces, are a
171   sequence of characters that follow the following format:

172   • The first character SHALL be an alphanumeric character, a digit, or an underscore.
173   • The subsequent characters MAY be alphanumeric, digits, spaces, or any of the following:

174   `_, @, ., -`
175   • The last character SHALL NOT be a space.

176   More precisely, a name must match the following regular expression (expressed with Java
177   metacharacter syntax):
178   `\A([\w]|[\w][\w@ .-]*[\w@.-]+)\z`

Cardinality

Trigger to Action

181   A single trigger can be configured to invoke multiple Actions.

Definitions

Activation

184   An invocation or "run" of an action results in an activation record that is identified by a unique
185   activation ID. The term Activation is short-hand for the creation of this record and its
186   information.

Repository

188   A location that provides storage for sets of files, as well as the history of changes made to those
189   files.

Project

191   A description of a software application which enables management of its design,
192   implementation, source control, monitoring and testing.

Application

194   A computer program designed to perform a group of coordinated functions, tasks, or activities
195   to achieve some result or user benefit.
196

197 *[Cloud] Service*

198 Any resource, including a functional task, that is provided over the Internet. This includes
199 delivery models such as *Platform as a Service* (PaaS), *Infrastructure as a* Service (IaaS), as well
200 as *Serverless*.

Specification

202 This specification utilizes the YAML language, a superset of JSON, which supports key features
203 for packaging descriptors and configuration information such as built-in data types, complex data
204 types, anchors (relational information), files, comments and can embed other data formats such
205 as JSON and XML easily.

YAML Types

207 Many of the types we use in this profile are *built-in* types from the YAML 1.2 specification (i.e.,
208 those identified by the "tag:yaml.org,2002" version tag).

209
210 The following table declares the valid YAML type URIs and aliases that SHALL be used when
211 defining parameters or properties within an OpenWhisk package manifest:
212

Type Name	Type URI	Notes
string	tag:yaml.org,2002:str (default)	Default type if no type provided
integer	tag:yaml.org,2002:int	Signed. Includes large integers (i.e., long type)
float	tag:yaml.org,2002:float	Signed. Includes large floating point values (i.e., double type)
boolean	tag:yaml.org,2002:bool	This specification uses lowercase 'true' and lowercase 'false'
timestamp	tag:yaml.org,2002:timestamp (see YAML-TS-1.1)	ISO 8601 compatible.
null	tag:yaml.org,2002:null	Different meaning than an empty string, map, list, etc.
version	tag:maven.apache.org:version (see Maven version)	Typically found in modern tooling (i.e., "package@version" or "package:version" format).
string256	long length strings (e.g., descriptions)	A string type limited to 256 characters.
string64	medium length strings (e.g., abstracts, hover text)	A string type limited to 64 characters.
string16	short length strings (e.g., small form-factor list displays)	A string type limited to 16 characters.

213 *Requirements*

214 • The 'string' type SHALL be the default type when not specified on a parameter or property
215 declaration.
216 • All 'boolean' values SHALL be lowercased (i.e., 'true' or 'false').

217 ## OpenWhisk Types

218 In addition to the YAML built-in types, OpenWhisk supports the types listed in the table below.
219 A complete description of each of these types is provided below.
220
221

Type Name	Description	Notes
json	The parameter value represents a JavaScript Object Notation (JSON) data object.	The deploy tool will validate the corresponding parameter value against JSON schema. Note: The implied schema for JSON the JSON Schema (see http://json-schema.org/).
scalar-unit	Convenience type for declaring common scalars that have an associated unit. For example, "10 msec.", "2 Gb", etc.)	See description below.
schema	The parameter itself is an OpenAPI Specifcation v2.0 **Schema Object** (in YAML formatt) with self-defining schema.	The schema declaration follows the OpenAPI v2.0 specification for Schema Objects (YAML format).. Specifically, see https://github.com/OAI/OpenAPI-Specification/blob/master/versions/2.0.md#schemaObject
object	The parameter itself is an object with the associated defined Parameters (schemas).	Parameters of this type would include a declaration of its constituting Parameter schema.

222

223 ### scalar-unit types

224 Scalar-unit types can be used to define scalar values along with a unit from the list of recognized
225 units (a subset of GNU units) provided below.

226 *Grammar*

```
<scalar> <unit>
```

227 In the above grammar, the pseudo values that appear in angle brackets have the following meaning:

228 • scalar: is a required scalar value (e.g., integer).
229 • unit: is a required unit value. The unit value MUST be type-compatible with the scalar value.

230 *Requirements*

231 • Whitespace: any number of spaces (including zero or none) SHALL be allowed between the scalar
232 value and the unit value.
233 • It SHALL be considered an error if either the scalar or unit portion is missing on a property or
234 attribute declaration derived from any scalar-unit type.

Recognized units for sizes (i.e., scalar-unit.size)

Unit	Description
B	byte
kB	kilobyte (1000 bytes)
MB	megabyte (1000000 bytes)
GB	gigabyte (1000000000 bytes)
TB	terabyte (1000000000000 bytes)

236 *Recognized units for times (i.e., scalar-unit.time)*

Unit	Description
d	days
h	hours
m	minutes
s	seconds
ms	milliseconds
us	microseconds

237 ### *Object type example*

238
239 The Object type allows for complex objects to be declared as parameters with an optional validateable schema.

```
inputs:
  person:
    type: object
    parameters:
```

240

241 ## Schema

242
243 This section defines all the essential schema used to describe OpenWhisk packages within a manifest.

244 ### *General Requirements*

245 • All field names in this specification SHALL be case sensitive.

246 ### *map schema*

247 The Map schema is used to define maps of key values within OpenWhisk entities.

248 *Single-line grammar*

```
{ <key_1>: <value_1>, ..., <key_n>: <value_n> }
```

249 *Multi-line grammar*

```
# Where 'key_n' is a type <string> and 'value_n' is type <any>.
<key_1>: <value_1>
...
<key_n>: <value_n>
```

250 *Examples*

251 *Single-line*

```
alert_levels: { "high": "red", "medium": "yellow", "low": green }
```

252 *Multi-line*

```
alert_levels:
   "high": "red"
   "medium": "yellow"
   "low": green
```

253

254 ***Parameter schema***

255 The Parameter schema is used to define input and/or output data to be used by OpenWhisk
256 entities for the purposes of validation.

257 *Fields*

Key Name	Required	Value Type	Default	Description
type	no	`<any>`	`string`	Optional valid type name or the parameter's value for validation purposes. By default, the type is `string`.
description	no	`string256`	N/A	Optional description of the Parameter.
value	no	`<any>`	N/A	The optional user supplied value for the parameter. Note: this is not the default value, but an explicit declaration which allows simple usage of the Manifest file without a Deployment file..
required	no	`boolean`	`true`	Optional indicator to declare the parameter as required (i.e., `true`) or optional (i.e., `false`).
default	no	`<any>`	N/A	Optional default value for the optional parameters. This value **MUST** be type compatible with the value declared on the parameter's `type` field.
status	no	`string`	`supported`	Optional status of the parameter (e.g., `deprecated`, `experimental`). By default a parameter is without a declared status is considered supported.
schema	no	`<schema>`	N/A	The optional schema if the '`type`' key has the value '`schema`'. The value would include a **Schema Object** (in YAML) as defined by the OpenAPI Specifcation v2.0. This object is based upon the JSON Schema Specification.

Key Name	Required	Value Type	Default	Description
properties	no	`<list of Parameter schema>`	N/A	The optional properties if the '`type`' key has the value '`object`'. Its value is a listing of Parameter schema from this specifcation.

258 *Requirements*

259 • The "schema" key's value MUST be compatible with the value provided on both the "type" and "value"
260 keys; otherwise, it is considered an error.

261 *Notes*

262 • The "type" key acknowledges some popular schema (e.g., JSON) to use when validating the value of
263 the parameter. In the future additional (schema) types may be added for convenience.

264 *Grammar*

265 *Single-line*

```
<parameterName>: <YAML type> | scalar-unit | json
```

266 • Where `<YAML type>` is inferred to be a YAML type as shown in the YAML Types section above (e.g.,
267 string, integer, float, boolean, etc.).

268 • If you wish the parser to validate against a different schema, then the multi-line grammar MUST be
269 used where the value would be supplied on the keyname "value" and the type (e.g., json) and/or
270 schema (e.g., OpenAPI) can be supplied

271 *Multi-line*

```
<parameterName>:
  type: <any>
  description: <string>
  required: <boolean>
  default: <any>
  status: <string>
  schema: <OpenAPI Schema Object>
```

272 *Status values*

Status Value	Description
supported (default)	Indicates the parameter is supported. This is the implied default status value for all parameters.
experimental	Indicates the parameter MAY be removed or changed in future versions.
deprecated	Indicates the parameter is no longer supported in the current version and MAY be ignored.

273

274 **Shared schema for all Entities**

275 The entity schema contains fields that are common to all OpenWhisk entities (e.g., Actions,
276 Triggers, Rules, etc.).

277 *Fields*

Key Name	Required	Value Type	Default	Description
version	yes	`version`	N/A	The required version for the Entity.
description	no	`string256`	N/A	The optional description for the Entity.
displayName	no	`string16`	N/A	This is the optional name that will be displayed on small form-factor devices.
annotations	no	**TBD**	N/A	The optional annotations for the Entity.
inputs	no	`list` of `parameter`	N/A	The optional ordered list inputs to the Entity.
outputs	no	`list` of `parameter`	N/A	The optional outputs from the Entity.

278 *Grammar*

```
version: <version>
description: <string>
annotations: <map of <string>>
inputs: <list of <parameter>>
outputs: <list of <parameter>>
```

279 *Requirements*

280 • Version values for all entities SHALL be provided.
281 • Non-required fields MAY be stored as "annotations" within the OpenWhisk framework after they
282 have been used for processing.
283 • Description string values SHALL be limited to 256 characters.
284 • DisplayName string values SHALL be limited to 16 characters.
285 • The lists of inputs and outputs MAY also be described as ordered lists (using the YAML '-' dash
286 convention).
287 • Annotations MAY be ignored by target consumers of the Manifest file as they are considered data
288 non-essential to the deployment of management of OpenWhisk entities themselves.
289 • Target consumers MAY preserve (persist) these values, but are not required to.
290 • For any OpenWhisk Entity, the maximum size of all Annotations SHALL be (TBD) characters.

291 *Notes*

292 • Input and output parameters are implemented as JSON Objects within the OpenWhisk framework.
293 • Several, non-normative Annotation keynames and allowed values for (principally for User Interface
294 (UI) design) may be defined below for optional usage.

295 **Action entity**

296 The Action entity schema contains the necessary information to deploy an OpenWhisk function
297 and define its deployment configurations, inputs and outputs.

298 *Fields*

Key Name	Required	Value Type	Default	Description
function	yes	`string`	N/A	Required source location (path inclusive) of the Action code either • Relative to the Package manifest file. • Relative to the specified Repository.
runtime	no	`string`	N/A	The required runtime name (and optional version) that the Action code requires for an execution environment. *Note: May be optional if tooling allowed to make assumptions about file extensions.*
limits	no	`map` of <limit keys and values>	N/A	Optional map of limit keys and their values. *See section "Valid limit keys" below for a listing of recognized keys and values.*
feed	no	`boolean`	`false`	Optional indicator that the Action supports the required parameters (and operations) to be run as a Feed Action.
web-export	no	`boolean`	`false`	Optionally, turns the Action into a "*web actions*" causing it to return HTTP content without use of an API Gateway.

299 *Requirements*

300 • The Action name (i.e., `<actionName>` MUST be less than or equal to 256 characters.
301 • The Action entity schema includes all general Entity Schema fields in addition to any fields declared
302   above.
303 • Supplying a `runtime` name without a version indicates that OpenWhisk SHOULD use the most
304   current version.
305 • Supplying a runtime *major version* without a *minor version* (et al.) indicates OpenWhisk SHOULD use
306   the most current *minor version*.
307 • Unrecognized `limit` keys (and their values) SHALL be ignored.
308 • Invalid values for known `limit` keys SHALL result in an error.
309 • If the Feed is a Feed Action (i.e., the `feed` key's value is set to `true`), it MUST support the following
310   parameters:
311   • **lifecycleEvent**: one of 'CREATE', 'DELETE', 'PAUSE', or 'UNPAUSE'
312   o   These operation names MAY be supplied in lowercase (i.e., 'create', 'delete', 'pause', etc.).
313   • **triggerName**: the fully-qualified name of the trigger which contains events produced from this
314   feed.
315   • **authKey**: the Basic auth. credentials of the OpenWhisk user who owns the trigger just
316   mentioned.

317 *Notes*

318 • The maximum code size for an Action currently must be less than 48 MB.
319 • The maximum payload size for an Action (i.e., POST content length or size) currently must be less
320   than 1 MB.
321 • The maximum parameter size for an Action currently must be less than 1 MB.

Valid Runtime names

323   The following runtime values are currently supported by the OpenWhisk platform.
324
325   Each of these runtimes also include additional built-in packages (or libraries) that have been
326   determined be useful for Actions surveyed and tested by the OpenWhisk platform.
327
328   These packages may vary by OpenWhisk release; examples of supported runtimes (as of August
329   2017) include:
330

Runtime value	OpenWhisk kind	image name	Description
`nodejs`	nodejs	nodejsaction:latest	Latest NodeJS runtime
`nodejs@6`	nodejs:6	nodejs6action:latest	Latest NodeJS 6 runtime
`java`, `java@8`	java	java8action:latest	Latest Java language runtime
`python`, `python@2`	python:2	python2action:latest	Latest Python 2 language runtime
`python@3`	python:3	python3action:latest	Latest Python 3 language runtime
`swift`, `swift@2`	swift	swiftaction:latest	Latest Swift 2 language runtime
`swift@3`	swift:3	swift3action:latest	Latest Swift 3 language runtime
`swift@3.1.1`	swift:3.1.1	action-swift-v3.1.1:latest	Latest Swift 3.1.1 language runtime
`php`	php:7.1	action-php-v7.1:latest	Latest PHP language runtime
`language:default`	N/A	N/A	Permit the OpenWhisk platform to select the correct default language runtime.

331   *Please note, if no value for runtime is supplied, the value 'language:default' will be assumed.*

332   *Recognized File extensions*

333   Although it is best practice to provide a runtime value when declaring an Action, it is not
334   required. In those cases, that a runtime is not provided, the package tooling will attempt to derive
335   the correct runtime based upon the the file extension for the Action's function (source code file).
336   The following file extensions are recognized and will be run on the latest version of
337   corresponding Runtime listed below:
338

File extension	Runtime used	Description
`.js`	nodejs	Latest Node.js runtime.
`.java`	java	Latest Java language runtime.
`.py`	python	Latest Python language runtime.
`.swift`	swift	Latest Swift language runtime.
.php	php	Latest PHP language runtime.

Valid Limit keys

Limit Keyname	Allowed values	Default value	Valid Range	Description
`timeout`	scalar-unit.time	60000 ms	[100 ms, 300000 ms]	The per-invocation Action timeout. Default unit is assumed to be milliseconds (ms).
`memorySize`	scalar-unit.size	256 MB	[128 MB, 512 MB]	The per-Action memory. Default unit is assumed to be in megabytes (MB).
`logSize`	scalar-unit.size	10 MB	[0 MB, 10 MB]	The action log size. Default unit is assumed to be in megabytes (MB).
`concurrentActivations`	integer	1000	*See description*	The maximum number of concurrent Action activations allowed (per-namespace). *Note: This value is not changeable via APIs at this time.*
`userInvocationRate`	integer	5000	*See description*	The maximum number of Action invocations allowed per user, per minute. *Note: This value is not changeable via APIs at this time.*
`codeSize`	scalar-unit.size	48 MB	*See description*	The maximum size of the Action code. *Note: This value is not changeable via APIs at this time.*
`parameterSize`	scalar-unit.size	1 MB	*See description*	The maximum size *Note: This value is not changeable via APIs at this time.*

340 *Notes*

341 The default values and ranges for limit configurations reflect the defaults for the OpenWhisk
342 platform (open source code). These values may be changed over time to reflect the open source
343 community consensus.

344 *Web Actions*

345 OpenWhisk can turn any Action into a "web action" causing it to return HTTP content without
346 use of an API Gateway. Simply supply a supported "type" extension to indicate which content
347 type is to be returned and indentified in the HTTP header (e.g., `.json`, `.html`, `.text` or `.http`).

348 Return values from the Action's function are used to construct the HTTP response. The
349 following response parameters are supported in the response object.

350   1. `headers`: a JSON object where the keys are header-names and the values are string
351   values for those headers (default is no headers).
352   2. `code`: a valid HTTP status code (default is 200 OK).
353   3. `body`: a string which is either plain text or a base64 encoded string (for binary data).

354 *Grammar*

```
# Note: the optional [.<type>] grammar is used for naming Web Actions.
<actionName>[.<type>]:
  <Entity schema> # Common to all OpenWhisk Entities
  function: <string>
  runtime: <name>[@<[range of ]version>]
  limits:
    <list of limit key-values>
  feed: <boolean> # default: false
```

355 *Example*

```
my_awesome_action:
  version: 1.0
  description: An awesome action written for node.js
  function: src/js/action.js
  runtime: nodejs@>0.12<6.0
  inputs:
    not_awesome_input_value:
      description: Some input string that is boring
      type: string
  outputs:
    awesome_output_value:
      description: Impressive output string
      type: string
  limits:
    memorySize: 512 kB
    logSize: 5 MB
```

356 **Sequence entity**

357 Actions can be composed into seqences to, in effect, form a new Action. The Sequence entity
358 allows for a simple, convenient way to describe them in the Package Manifest.

359 *Fields*

Key Name	Required	Value Type	Default	Description
actions	yes	list of Action	N/A	• The required list of two or more actions

360 *Requirements*

361   • The comma separated list of Actions on the actions key SHALL imply the order of the sequence (from
362   left, to right).
363   • There MUST be two (2) or more actions declared in the sequence.

364 *Notes*

365   • The sequences key exists for convenience; however, it is just one possible instance of a composition
366   of Actions. The composition entity is provided for not only describing sequences, but also for other
367   (future) compositions and additional information needed to compose them. For example, the

368 composition entity allows for more complex mappings of input and output parameters between
369 Actions.

370 *Grammar*

```
sequences:
  <sequence name>:
     actions: <list of action names>
  ...
```

371 *Example*

```
sequences:
  newbot:
    actions: oauth/login, newbot-setup, newbot-greeting
```

372

373 ### *Trigger entity*

374 The Trigger entity schema contains the necessary information to describe the stream of events
375 that it represents. For more information see: "Creating Triggers and Rules".

376 *Fields*

Key Name	Required	Value Type	Default	Description
feed	no	string	N/A	The optional name of the Feed associated with the Trigger.
events	no	list of Event	N/A	The optional list of valid Event schema the trigger supports. OpenWhisk would validate incoming Event data for conformance against any Event schema declared under this key. Note: This feature is not supported at this time. This is viewed as a possible feature that may be implemented along with configurable options for handling of invalid events.

377

378 *Requirements*

379 • The Trigger name (i.e., `<triggerName>` MUST be less than or equal to 256 characters.
380 • The Trigger entity schema includes all general Entity Schema fields in addition to any fields declared
381 above.

382 *Notes*

383 • The Trigger entity within the OpenWhisk programming model is considered outside the scope of the
384 Package (although there are discussions about changing this in the future). This means that Trigger
385 and API information will not be returned when using the OpenWhisk Package API:
386 • `wsk package list <package name>`
387 • However, it may be obtained using the Trigger API:
388 • `wsk trigger list -v`

389 *Grammar*

```
<triggerName>:
  <Entity schema> # Common to all OpenWhisk Entities
  feed: my_feed
```

390 ## Rule entity

391 The Rule entity schema contains the information necessary to associates one trigger with one
392 action, with every firing of the trigger causing the corresponding action to be invoked with the
393 trigger event as input. For more information see: "Creating Triggers and Rules".

394 *Fields*

Key Name	Required	Value Type	Default	Description
trigger	yes	string	N/A	Required name of the Trigger the Rule applies to.
action	yes	string	N/A	Required name of the Action the Rule applies to.
rule	no	regex	true	The optional regular expression that determines if the Action is fired. Note: In this version of the specification, only the expression "true" is currently supported.

395 *Requirements*

396 • The Rule name (i.e., `<ruleName>`) MUST be less than or equal to 256 characters.
397 • The Rule entity schema includes all general Entity Schema fields in addition to any fields declared
398 above.

399 *Grammar*

```
<ruleName>:
  <Entity schema> # Common to all OpenWhisk Entities
  trigger: <string>
  action: <string>
  rule: <regex>  # "true" supported at this time
```

400 *Example*

```
my_rule:
  desription: Enable events for my Action
  trigger: my_trigger
  action: my_action
```

401 ## Composition entity

402 The Composition entity schema contains information to declare compositions of OpenWhisk
403 Actions. Currently, this includes Action Sequences where Actions can be composed of two or
404 more existing Actions.

405 *Fields*

Key Name	Required	Value Type	Default	Description
type	no	`string`	`sequence`	The optional type of Action composition. *Note: currently only 'sequence' is supported.*
inputs	no	`list` of `parameter`	N/A	The optional list of parameters for the Action composition (e.g., Action Sequence).
sequence	no	`ordered list` of `Action` (names)	N/A	The optional expression that describes the connections between the Actions that comprise the Action sequence composition.
parameterMappings	no	TBD	N/A	The optional expression that describes the mappings of parameter (names and values) betweens the outputs of one Action to the inputs of another Action. Note: Currently, mappings are not supported and JSON objects are passed between each Action in a sequence. At this time, it is assumed that the Actions in a sequence are designed to work together with no output to input mappings being performed by the OpenWhisk platform.

406 *Requirements*

407 • The Composition name (i.e., `<compositionName>` MUST be less than or equal to 256 characters.
408 • The Composition entity schema includes all general Entity Schema fields in addition to any fields
409 declared above.

410 *Grammar*

```
<compositionName>:
  <Entity schema> # Common to all OpenWhisk Entities
  type: <string>
  inputs: <list of parameters>
  sequence:
    - <order list of action names>
  parameterMappings:
    # TBD. This is a future use case.
```

411 *Example*

```
my_action_sequence:
  type: sequence
  sequence:
    - action_1
    - action_2
    - action_3
  inputs:
    simple_input_string: string
  outputs:
    annotated_output_string: string
```

412 *Feed entity*

413 The OpenWhisk Feed entity schema contains the information necessary to reference a
414 configurable service that works with an existing network accessible service to produce events on
415 its behalf thereby acting as an Event Source.
416
417 These are standalone services unto themselves which the OpenWhisk platform does not currently
418 deploy and run from an OpenWhisk Package. At this time, the Package Manifest simply provides
419 the information to access, configure and manage (via lifecycle operations) the Feed service that
420 is already running elsewhere.

421 *Fields*

Key Name	Required	Value Type	Default	Description
location	no	string	N/A	The URL for the Feed service which can be used by the OpenWhisk platform or registration and conifguration.
credential	no	string	N/A	Contains either: • A credential string. • The optional name of a credential (e.g., token) that must be used to acceess the Feed service. Note: this would be defined elsewhere, perhaps as an input parameter to the Package.
operations	no	list of operations	N/A	The list of operations (i.e., APIs) the Feed supports on the URL provided described, by default, using the OpenAPI (f.k.a. "Swagger") specification schema.
operation_type	no	openwhisk | openapi@<version>	openwhisk	The specification format for the operation definitions.
action	no	string	N/A	The optional name of the Action if this is a Feed Action, that is, the Feed service implementaion is an OpenWhisk Action.

422 *Requirements*

423 • The Feed name (i.e., `<feedName>` MUST be less than or equal to 256 characters.
424 • The Feed entity schema includes all general Entity Schema fields in addition to any fields declared
425 above.
426 • If the `action` field is set, the corresponding Action defintion and function (code) MUST be a valid
427 Feed Action.
428 • The location and credential SHOULD be supplied if the Feed is not a Feed action from the Deployment
429 File.
430 • Operation names in manifests MAY be lower or upper cased (e.g., "create" or "CREATE").

431 *Grammar*

```
<feedName>:
  <Entity schema> # Common to all OpenWhisk Entities
  location: <string>
  credential: <Credential>
```

```
    operations:
      <list of operations>
    action: <string>
```

432 *Example*

433 The following example shows the mandatory operations for Feed Actions.

434

```
my_feed:
  description: A simple event feed
  location: https://my.company.com/services/eventHub
  # Reference to a credential defined elsewhere in manifest
  credential: my_credential
  operations:
    # Note: operation names in manifests MAY be lower or upper cased.
    create | CREATE:
      inputs:
        <parameters>
    delete | DELETE:
      inputs:
        <parameters>
    pause | PAUSE:
      inputs:
        <parameters>
    unpause | UNPAUSE:
      inputs:
        <parameters>
    # Additional, optional operations
    ...
```

435 *Discussion*

436 For a description of types of Feeds and why they exist, please see
437 https://github.com/openwhisk/openwhisk/blob/master/docs/feeds.md.

438 *Feed Actions*

439 OpenWhisk supports an open API, where any user can expose an event producer service as a
440 **feed** in a **package**. This section describes architectural and implementation options for providing
441 your own feed.

442 *Feed actions and Lifecycle Operations*

443 The *feed action* is a normal OpenWhisk *action*, but it should accept the following parameters:
444   • **lifecycleEvent**: one of 'CREATE', 'DELETE', 'PAUSE', or 'UNPAUSE'
445   • **triggerName**: the fully-qualified name of the trigger which contains events produced from this feed.
446   • **authKey**: the Basic auth. credentials of the OpenWhisk user who owns the trigger just mentioned

447 The feed action can also accept any other parameters it needs to manage the feed. For example,
448 the Cloudant changes feed action expects to receive parameters including *'dbname'*, *'username'*,
449 etc.

API entity

This entity allows manifests to link Actions to be made available as HTTP-based API endpoints
as supported by the API Gateway service of OpenWhisk.

This entity declaration is intended to provide grammar for the experimental API *(see*
https://github.com/apache/incubator-openwhisk/blob/master/docs/apigateway.md and shown
using a "book club" example:

Example

```
$ wsk api create -n "Book Club" /club /books get getBooks
$ wsk api create /club /books post postBooks
$ wsk api create /club /books put putBooks
$ wsk api create /club /books delete deleteBooks
```

the above would translate to the following grammars in the pkg. spec. to a new-top level
keyname "apis" in the manifest:

Grammar

```
apis:
  <API name>:                    # descriptive name
    description: <string>        # optional, description
    <basepath>:                  # shared basepath
      <path>:
         <action name>: get | post | put | delete
         ...
      ...
```

Note

• There can be more than one set of named <path> actions under the same <basepath>.

Example

A somewhat simplified grammar is also supported that allows single-line definition of Actions
(names) along with their HTTP verbs.

```
apis:
  book-club:
    club:
      books:
        getBooks: get
        postBooks: post
        putBooks: put
        deleteBooks: delete
      members:
        listMembers: get
```

Requirements

• The API entity's name (i.e., `<API Name>`) MUST be less than or equal to 256 characters.

Notes

469   •   The API entity within the OpenWhisk programming model is considered outside the scope of the
470   Package. This means that API information will not be returned when using the OpenWhisk Package
471   API:
472   •   `wsk package list <package name>`
473   •   However, it may be obtained using the Trigger API:
474   •   `wsk api list -v`

475   *Package entity*

476   The Package entity schema is used to define an OpenWhisk package within a manifest.

477   *Fields*

Key Name	Required	Value Type	Default	Description
license	yes	`string`	`unlicensed`	The required value that indicates the type of license the Package is governed by.
credential	no	`string`	N/A	The optional Credential used for all entities within the Package. The value is either: Contains either: • A credential string. • The optional name of a credential (e.g., token) that is defined elsewhere.
dependencies	no	list of Dependency	N/A	The optional list of external OpenWhisk packages the manifest needs deployed before it can be deployed.
repositories	no	list of `Repository`	N/A	The optional list of external repositories that contain functions and other artifacts that can be found by tooling.
actions	no	list of `Action`	N/A	Optional list of OpenWhisk Action entity definitions.
sequences	no	list of Sequence	N/A	Optional list of OpenWhisk Sequence entity definitions.
triggers	no	list of `Trigger`	N/A	Optional list of OpenWhisk Trigger entity definitions.
rules	no	list of `Rule`	N/A	Optional list of OpenWhisk Rule entity definitions.
feeds	no	list of `Feed`	N/A	Optional list of OpenWhisk Feed entity definitions.
compositions	no	list of `Composition`	N/A	Optional list of OpenWhisk Composition entity definitions.
apis	no	list of API	N/A	Optional list of API entity definitions.

478   *Requirements*

479   •   The Package `name` MUST be less than or equal to 256 characters.
480   •   The Package entity schema includes all general Entity Schema fields in addition to any fields declared
481   above.

482 • A valid Package `license` value MUST be one of the Linux SPDX license values; for example: `Apache-`
483 `2.0` or `GPL-2.0+`, or the value 'unlicensed'.
484 • Multiple (mixed) licenses MAY be described using using NPM SPDX license syntax.
485 • A valid Package entity MUST have one or more valid Actions defined.

486 *Notes*

487 • The Trigger and API entities within the OpenWhisk programming model are considered outside the
488 scope of the Package. This means that Trigger and API information will not be returned when using
489 the OpenWhisk Package API:
490 • `wsk package list <package name>`
491 • However, their information may be retrieved using respectively:
492 • `wsk trigger list -v`
493 • `wsk api list -v`

494 *Grammar*

```
<packageName>:
    <Entity schema> # Common to all OpenWhisk Entities
    license: <string>
    repositories: <list of Repository>
    actions: <list of Action>
    sequences: <list of Sequence>
    triggers: <list of Trigger>
    rules: <list of Rule>
    feeds: <list of Feed>
    compositions: <list of Composition>
    apis: <list of API>
```

495 *Example*

```
my_whisk_package:
  description: A complete package for my awesome action to be deployed
  version: 1.2.0
  license: Apache-2.0
  actions:
    my_awsome_action:
      <Action schema>
  triggers:
    trigger_for_awesome_action:
      <Trigger schema>
  rules:
    rule_for_awesome_action>
      <Rule schema>
```

496   **Extended Schema**

497   *Dependencies*

498   The dependencies section allows you to declare other OpenWhisk packages that your application
499   or project (manifest) are dependent on. A Dependency is used to declare these other packages
500   which deployment tools can use to automate installation of these pre-requisites.

501   *Fields*

Key Name	Required	Value Type	Default	Description
location	yes	`string`	`N/A`	The required location of the package.
version	yes	`version`	`N/A`	The required version of the package.
inputs	no	`various`	`N/A`	The optional Inputs to the package.

502   *Requirements*

503   •   No additional requirements.

504   *Notes*

505   •   The 'version' parameter is currently used to specify a branch in GitHub and defaults to "master", this
506   behavior may change in upcoming releases of the specification.

507   *Grammar*

```
<package_name>:
  location: <GitHub URL> |
  version: 1.0.1
  inputs:
    <list of inputs>
```

508   *Example*

```
dependencies:
  status_update:
    location: github.com/myrepo/statusupdate
        version: 1.0.
  database_pkg:
    location: /whisk.system/couchdb
    inputs:
      dbname: MyAppsDB
```

509

510   *Repository*

511   A repository defines a named external repository which contains (Action) code or other artifacts
512   package processors can access during deployment.

513 *Fields*

Key Name	Required	Value Type	Default	Description
url	yes	`string`	N/A	Required URL for the Repository.
description	no	`string256`	N/A	Optional description for the Repository.
credential	no	`string`	N/A	Optional name of a Credential defined in the Package that can be used to access the Repository.

514

515 *Requirements*

516 •   The Repository name (i.e., `<repositoryName>` MUST be less than or equal to 256 characters.
517 •   Description string values SHALL be limited to 256 characters.

518 *Grammar*

519 *Single-line (no credential)*

```
<repositoryName>: <repository_address>
```

520 *Multi-line*

```
<repositoryName>:
  description: <string256>
  url: <string>
  credential: <Credential>
```

521 *Example*

```
my_code_repo:
  description: My project's code repository in GitHub
  url: https://github.com/openwhisk/openwhisk-package-rss
```

522

523 **Credential**

524 A Credential is used to define credentials used to access network accessible resources. Fields

Key Name	Required	Value Type	Default	Description
protocol	no	`string`	N/A	Optional protocol name used to indicate the authorization protocol to be used with the Credential's token and other values.
tokenType	yes	`string`	password	Required token type used to indicate the type (format) of the token string within the supported types allowed by the protocol.
token	yes	`string`	N/A	Required token used as a credential for authorization or access to a networked resource.
description	no	`string256`	N/A	Optional description for the Credential.

Key Name	Required	Value Type	Default	Description
keys	no	`map` of `string`	N/A	Optional list of protocol-specific keys or assertions.

525

527   • The Credential name (i.e., `<credentialName>` MUST be less than or equal to 256 characters.
528   • Description string values SHALL be limited to 256 characters.

Valid protocol values
529

Protocol Value	Valid Token Type Values	Description
`plain`	N/A	Basic (plain text) username-password (no standard).
`http`	basic_auth	HTTP Basic Authentication Protocol.
`xauth`	X-Auth-Token	HTTP Extended Authentication Protocol (base-64 encoded Tokens).
`oauth`	bearer	Oauth 2.0 Protocol
`ssh`	identifier	SSH Keypair protocol (e.g., as used in OpenStack)

530

Grammar
531

```
Credential:
  type: Object
  properties:
    protocol:
      type: string
      required: false
    tokenType:
      type: string
      default: password
    token:
      type: string
    keys:
      type: map
      required: false
      entry_schema:
        type: string
    user:
      type: string
      required: false
```

Notes
532

533   • The use of transparent user names (IDs) or passwords are not considered best practice.

534 *Examples*

535 *Plain username-password (no standardized protocol)*

```
inputs:
  my_credential:
    type: Credential
      properties:
        user: my_username
        token: my_password
```

536 *HTTP Basic access authentication*

```
inputs:
  my_credential:
    type: Credential
    description: Basic auth. where <username>:<password> are a single string
    properties:
      protocol: http
      token_type: basic_auth
      # Note: this would be base64 encoded before transmission by any impl.
      token: myusername:mypassword
```

537 *X-Auth-Token*

```
inputs:
  my_credential:
    type: Credential
    description: X-Auth-Token, encoded in Base64
    properties:
      protocol: xauth
      token_type: X-Auth-Token
      # token encoded in Base64
      token: 604bbe45ac7143a79e14f3158df67091
```

538 *OAuth bearer token*

```
inputs:
  my_credential:
    type: Credential
    properties:
      protocol: oauth2
      token_type: bearer
      # token encoded in Base64
      token: 8ao9nE2DEjr1zCsicWMpBC
```

539 *SSH Keypair*

```
inputs:
  my_ssh_keypair:
    type: Credential
    properties:
      protocol: ssh
      token_type: identifier
      # token is a reference (ID) to an existing keypair (already installed)
```

```
            token: <keypair_id>
```
540

Package Artifacts

Package Manifest File

543 The Package Manifest file is the primary OpenWhisk Entity used to describe an OpenWhisk
544 Package and all necessary **schema** and **file** information needed for deployment. It contains the
545 Package entity schema described above.

Deployment File

547 The Deployment file is used in conjunction with a corresponding Package Manifest file to
548 provide configuration information (e.g., input parameters, authorization credentials, etc.) needed
549 to deploy, configure and run an OpenWhisk Package for a target Cloud environment.
550 Fields
551
552 The manifest and Deployment files are comprised of the following entities:

Application

554 An optional, top-level key that describes a set of related Packages that together comprise a
555 higher-order application.

556 *Fields*

Key Name	Required	Value Type	Default	Description
name	no	string256	N/A	The optional name of the application.
namespace	no	string	N/A	The optional namespace for the application (and default namesapce for its packages where not specified).
credential	no	string	N/A	The optional credential for the application (and default credential for its packages where not specified).
packages	yes	list of package	N/A	The required list of one or more packages.

557

558 *Grammar*

```
application:
  name: <string256>
  namespace: <string>
  credential: <string>
  packages:
    <list of package>
```

559

Requirements

561   •   The keys under the application key (e.g., name, namespace, credential and packages) are only used in
562   a manifest or deployment file if the optional application key is used.

563 *Notes*

564   •   Currently, the OpenWhisk platform does not recognize the Application entity as part of the
565   programming model; it exists as a higher order grouping concept only in this specification. Therefore
566   there is no data stored within OpenWhisk for the Application entity,

567 *Example*

```
application:
  name: greetings
  namespace: /mycompany/greetings/
  credential: 1234-5678-90abcdef-0000
  packages:
    helloworld:
      inputs:
        city: Boston
      actions:
        hello:
          inputs: # input bindings
            personName: Paul
    ...
```

568

569 *Notes*

570   •   A common use would be to associate a namespace (i.e., a target namespace binding) or cedential to
571   an application and all included packages automatically inherit that namespace (if applied at that
572   level) unless otherwise provided (similar to style inheritance in CSS).
573   •   The application name would be treated as metadata, perhaps stored in the annotations for the
574   contained entities.

575 ### *Setting values using ($) dollar notation*

576 In the Deployment file, a parameter value may be set from the local execution environment by
577 using the dollar ($) notation to denote names of local environment variables which supply the
578 value to be inserted at execution time.

579 *Syntax*

```
<parameter>: $<local environment variable name>
```

580 *Example*

```
  ...
    inputs:
      userName: $DEFAULT_USERNAME
```

Requirements

582   • Processors or tooling that encounter ($) Dollar notation and are unable to locate the value in the
583   execution environment SHOULD resolve the value to be the default value for the type (e.g., an empty
584   string for type string).

585   *Notes*

586   • Processors or tooling that encounter ($) Dollar notation for values should attempt to locate the
587   corresponding named variables set into the local execution environment (e.g., where the tool was
588   invoked) and assign its value to the named input parameter for the OpenWhisk entity.
589   • This specification does not currently consider using this notation for other than simple data types
590   (i.e., we support this mechanism for values such as strings, integers, floats, etc.) at this time.

Scenarios and Use cases

Usage Scenarios

User background

The following assumptions about the users referenced in the usage scenarios:

- Experienced developer; knows Java, Node, SQL, REST principles and basic DevOps processes; uses IDEs to develop code locally.
- Limited exposure to Serverless, but interested in trying new technologies that might improve productivity.

Scenario 1: Clone and Create

Deploy an OpenWhisk app (project, set of entities, package, ...) discovered on github. The developer…

1. discovers an interesting git repo containing an OpenWhisk app (project, set of entities, package, ...)
2. clones the repo to local disk.
3. He pushes (deploys) it into one of his OpenWhisk namespaces
4. He checks out the app's behavior using OpenWhisk CLI or OpenWhisk UI

Notes

- while this scenario allows to use the manifest file as a "black box" the manifest format can influence the user experience of a developer trying to read it and understand what it does

Scenario 2: Pushing Updates with versioning

Change a cloned repo that he previously pushed into one of his namespaces. The developer…

1. changes the local repo by editing code and adding and changing entity specifications using local tools (editors, IDEs, ...).
2. bumps version number for package.
3. pushes his updates into the namespace so that the existing entities are changed accordingly.

Scenario 3: Start New Repo with Manifest

Start a new OpenWhisk app (project, set of entities) from scratch. The developer…

1. code files for the actions (e.g. *action1.js, action2.js, action3.js)*
2. creates a LICENSE.*txt file*

626   3. Creates a **Manifest File** that specifies the set of OpenWhisk entities and their relations
627   (e.g. *manifest.yml).*   It also references the LICENSE.txt file.
628   4. initializes and uploads the set of files as a new git repo.
629

630   *Notes:*

631   •   Creating the initial manifest file should be supported by providing an empty template
632   with syntax examples and other helpful comments

633   *Scenario 4: Export into Repository*

634   Share an existing OpenWhisk app (project, set of entities) with others
635   so that they can deploy and change it for their purposes. The developer…

636   1. exports a defined set of entities (a whole namespace?) into a set of files that includes code
637   files, and generated manifest, LICENSE.txt and README files.
638   2. initializes and uploads the set of files as a new git repo.
639   Example: `git init` … etc.

640   *Scenario 5: Discovery and Import from object store*

641   Discover an OpenWhisk package (manifest) co-located with data in an Object storage service.
642   This package would include a description of the Actions, Triggers, Rules and Event Sources (or
643   Feeds) necessary to interact with data it is associated with directly from the Object storage
644   repository; thus allowing anyone with access to the data an immediate way to interact and use the
645   data via the OpenWhisk Serverless platform.

646   Schema Use Cases

647   "Hello world"

648   "Hello world" is a simple use case which will accept a string parameter and return a "Hello
649   world" if the parameter is null or "Hello + <string>" if the string parameter is not null.

650   *Manifest Files*

651   *Example 1: No parameter descriptions*

```
helloworld:
  version: 1.0
  license: Apache-2.0
  actions:
    hello:
      version: 1.0
      function: src/hello/hello.js
      inputs:
        personName: string
```

```
     outputs:
       greeting_string: string
```

652 *Defaults discussion*

653 This specification places an emphasis on simplicity for the casual developer who may wish to
654 hand-code a Manifest and/or Deployment File; however, it also provides a robust optional
655 schema that can be advantaged when integrating with larger application projects using design
656 and development tooling such as IDEs.
657
658 In the above example, please note the following intelligent defaults would be applied by a
659 deployment tooling authored using this speification:
660 • The runtime (i.e., `runtime: nodejs`) is found from the .js extension on the Action function's
661 filename.

662 *Example 2: with parameter descriptions*

```
helloworld:
  version: 1.0
  license: Apache-2.0
  actions:
    hello:
      version: 1.0
      function: src/hello/hello.js
      runtime: nodejs@6
      inputs:
        personName:
          type: string
          description: input person name
      outputs:
        greeting_string:
          type: string
          description: output greeting string
```

663 ## Basic Trigger and Rule

664 This use case will demonstrate how rules and triggers are configured in manifest and deployment
665 file. It will use the previous "helloworld" action, create a rule to associate a trigger with it.

666 *Manifest File*

```
helloRules:
  version: 1.0
  license: Apache-2.0
  actions:
    hello:
      version: 1.0
      function: src/hello/hello.js
      runtime: nodejs
      inputs:
        personName: string
      outputs:
```

```
        greeting_string: string

  triggers:
    locationUpdate:
      inputs:
        name: string
        place: string

  rules:
    myRule:
      trigger: locationUpdate
      action: hello
```

667   *Deployment File*

```
packages:
  helloRules:
    triggers:
      locationUpdate:
        inputs:
          name: Henry
          place: Washington, D.C.
```

668

669   Github feed

670   This use case will install a feed to fire a trigger when there is activity in a specified GitHub
671   repository.

672   *Manifest File*

```
git_webhook:
  version: 1.0
  license: Apache-2.0
  feeds:
    webhook_feed:
      version: 1.0
      function: github/webhook.js
      runtime: nodejs@6
      inputs:
        username:
          type: string
          description: github username
        repository:
          type: string
          description: url of github repository
        accessToken:
          type: string
          description: GitHub personal access token
        events:
          type: string
          description: the github event type
```

```
   triggers:
     webhook_trigger:
      action: webhook_feed
```

673 *Deployment File*

```
packages:
  git_webhook:
    triggers:
      webhook_trigger:
        inputs:
          username: daisy
          repository: https://github.com/openwhisk/wsktool.git
          accessToken:
          events:push
```

674

Github feed advanced

676 This use case use the Github feed to create a trigger. When there is any push event happened, it
677 will send a notification email.

678 *Manifest File*

```
git_webhook:
  version: 1.0
  license: Apache-2.0
  action:
    emailNotifier:
      version: 1.0
      function: src/sendemail.js
      runtime: nodejs
      inputs:
        email: string
        title: string
  rules:
    githubNotifier:
      trigger: webhook_trigger
      action: emailNotifier
```
679 *Deployment File*

```
packages:
  git_webhook:
    feeds:
      webhook_feed:
        inputs:
          email: daisy@company.com
          title: Github Push Notification
```

680

681 **RSS Package**

682 The RSS package provides RSS/ATOM feeds which can receive events when a new feed item is
683 available. It also defines a trigger to listen to a specific RSS feed. It describes the OpenWhisk
684 package reposited here:
685 https://github.com/openwhisk/openwhisk-package-rss.
686

687

688 *Manifest File*

689 *with inline values (no Deployment File)*

690 This example makes use of in-line "values" where the developer does not intend to use a separate
691 Deployment file:

```
rss:
  version: 1.0
  license: Apache-2
  description: RSS Feed package
  inputs:
    provider_endpoint:
      value: http://localhost:8080/rss
      type: string
      description: Feed provider endpoint

  feeds:
    rss_feed:
      version: 1.0
      function: feeds/feed.js
      runtime: nodejs@6
      inputs:
        url:
          type: string
          description: url to RSS feed
          value: http://rss.nytimes.com/services/xml/rss/nyt/HomePage.xml
        pollingInterval:
          type: string
          description: Interval at which polling is performed
          value: 2h
```

```
        filter:
          type: string
          description: Comma separated list of keywords to filter on

    triggers:
      rss_trigger:
        action: rss_feed
```

692

Deployment File

694 Alternatively, a Deployment File could have provided the same values (bindings) in this way:

```
packages:
  rss:
    inputs:
      provider_endpoint: http://localhost:8080/rss

    feeds:
      rss_feed:
        inputs:
          url: http://rss.nytimes.com/services/xml/rss/nyt/HomePage.xml
          pollingInterval: 2h
```

695

696 Using such a deployment file, allows for more flexibility and the resulting Manifest file would
697 not have needed any '`value`' fields.

Polygon Tracking

699 This use case describes a microservice composition using Cloudant and a Push Notification
700 service to enable location tracking for a mobile application. The composition uses Cloudant to
701 store polygons that describe regions of interests, and the latest known location of a mobile user.
702 When either the polygon set or location set gets updated, we use the Cloudant Geo capabilities to
703 quickly determine if the new item satisfies a geo query like "is covered by" or "is contained in".
704 If so, a push notification is sent to the user.

705 *Manifest File:*

```
application:
  name: PolygonTracking
  namespace: polytrack

  packages:
    polytrack:

      triggers:
        pointUpdate:
          <feed>

        polygonUpdate:
          <feed>
```

```
actions:
  superpush:
    inputs:
      appId: string
      appSecret: string

  pointGeoQuery:
    inputs:
      username: string
      password: string
      host: string
      dbName: string
      ddoc: string
      iName: string
      relation: string
    outputs:
      cloudantResp: json

  createPushParamsFromPointUpdate:
    <mapper>

  polygonGeoQuery:
    inputs:
      username: string
      password: string
      host: string
      dbName: string
      ddoc: string
      iName: string
      relation: string
    outputs:
      cloudantResp: json

  createPushParamsFromPolygonUpdate:
    <mapper>

Rules:
  whenPointUpdate:
    trigger:
      pointUpdate
    action:
      handlePointUpdate
  whenPointUpdate:
    trigger:
      polygonUpdate
    action:
      handlePolygonUpdate

Composition:
  handlePolygonUpdate:
    sequence:
createGeoQueryFromPolygonUpdate,polygonGeoQuery,createPushParamsFromPolygo
nUpdate,superpush
```

Deployment File:

```
application:
  name: PolygonTracking
  namespace: polytrack

  packages:

    myCloudant:
      <bind to Cloudant at whisk.system/Cloudant>

    polytrack:
      credential: ABDCF
      inputs:
        PUSHAPPID=12345
        PUSHAPPSECRET=987654
        COVEREDBY='covered_by'
        COVERS='covers'
        DESIGNDOC='geodd'
        GEOIDX='geoidx'
        CLOUDANT_username=myname
        CLOUDANT_password=mypassword
        CLOUDANT_host=myhost.cloudant.com
        POLYDB=weatherpolygons
        USERLOCDB=userlocation

      triggers:
        pointUpdate:
          <feed>
          inputs:
            dbname: $USERLOCALDB
            includeDoc: true
        polygonUpdate:
          <feed>
          inputs:
            dbname: $USERLOCDB
            includeDoc: true

      actions:
        superpush:
          inputs:
            appId: $PUSHAPPID
            appSecret: $PUSHAPPSECRET
        pointGeoQuery:
          inputs:
            designDoc: $DESIGNDOC
            indexName: $GEOIDX
            relation: $COVEREDBY
            username: $CLOUDANT_username
            password: $CLOUDANT_password
```

```
            host: $CLOUDANT_host
            dbName: $POLYDB
        polygonGeoQuery:
          inputs:
            designDoc: $DESIGNDOC
            indexName: $GEOIDX
            relation: $COVERS
            username: $CLOUDANT_username
            password: $CLOUDANT_password
            host: $CLOUDANT_host
            dbName: $POLYDB
```
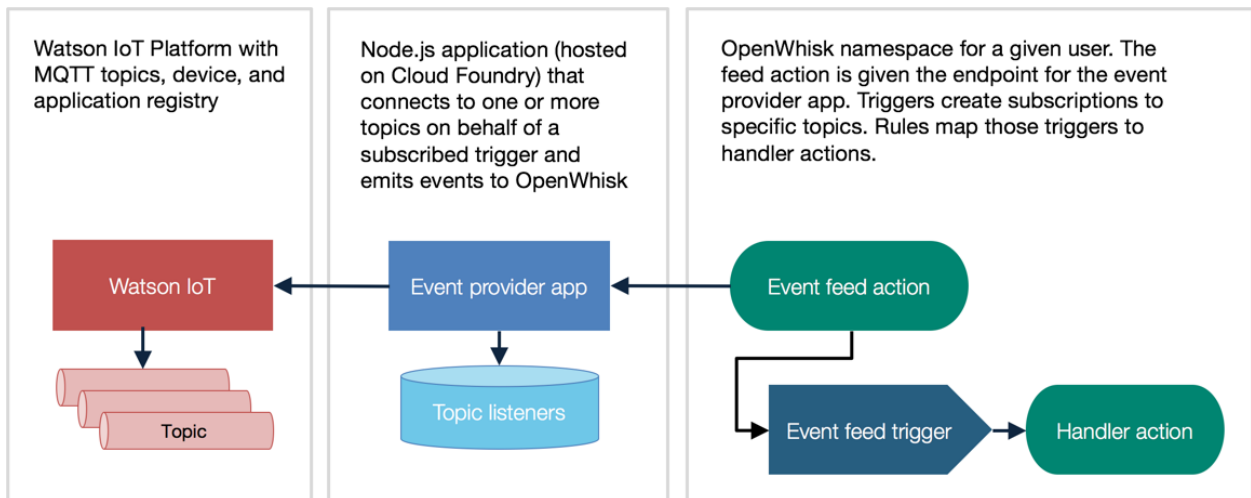

707

MQTT Package (tailored for Watson IoT)

709 The MQTT package that integrates with Watson IoT provides message topic feeds which can
710 receive events when a message is published. It also defines a trigger to listen to a specific MQTT
711 topic It describes the OpenWhisk package reposited here: https://github.com/krook/openwhisk-
712 package-mqtt-watson.

713

714
715

Manifest File

717 *with inline values (no Deployment File)*

718 This example makes use of in-line "values" where the developer does not intend to use a separate
719 Deployment file:

```
mqtt_watson:
  version: 1.0
  license: Apache-2
  description: MQTT Feed package for Watson IoT
  inputs:
    provider_endpoint:
      value: http://localhost:8080/mqtt-watson
```

```
        type: string
        description: Feed provider endpoint

    feeds:
      mqtt_watson_feed:
        version: 1.0
        function: feeds/feed-action.js
        runtime: nodejs@6
        inputs:
          url:
            type: string
            description: URL to Watson IoT MQTT feed
            value: ssl://a-123xyz.messaging.internetofthings.ibmcloud.com:8883
          topic:
            type: string
            description: Topic subscription
            value: iot-2/type/+/id/+/evt/+/fmt/json
          apiKey:
            type: string
            description: Watson IoT API key
            value: a-123xyz
          apiToken:
            type: string
            description: Watson IoT API token
            value: +-derpbog
          client:
            type: string
            description: Application client id
            value: a:12e45g:mqttapp

    triggers:
      mqtt_watson_trigger:
        action: mqtt_watson_feed
```

720

Deployment File

722   Alternatively, a Deployment File could have provided the same values (bindings) in this way:

```
packages:
  mqtt_watson:
    inputs:
      provider_endpoint: http://localhost:8080/mqtt-watson

    feeds:
      mqtt_watson_feed:
        inputs:
          url: ssl://a-123xyz.messaging.internetofthings.ibmcloud.com:8883
          topic: iot-2/type/+/id/+/evt/+/fmt/json
          apiKey: a-123xyz
          apiToken: +-derpbog
          client: a:12e45g:mqttapp
```

723

724   Using such a deployment file, allows for more flexibility and the resulting Manifest file would
725   not have needed any '`value`' fields.

726

Check deposit processing with optical character recognition

728   This use case demonstrates an event-driven architecture that processes the deposit of checks to a
729   bank account using optical character recognition. It relies on Cloudant and SoftLayer Object
730   Storage. On premises, it could use CouchDB and OpenStack Swift. Other storage services could
731   include FileNet or Cleversafe. Tesseract provides the OCR library.

732

733   This application uses a set of actions and triggers linked by rules to process images that are
734   added to an object storage service. When new checks are detected a workflow downloads,
735   resizes, archives, and reads the checks then it invokes an external system to handle the
736   transaction.

737

738

Manifest File:
```
application:
  name: OpenChecks
  namespace: openchecks

  packages:
    openchecks:

    triggers:
      poll-for-incoming-checks:
        inputs:
          cron: string
          maxTriggers: integer

      check-ready-to-scan:
        inputs:
          dbname: string
          includDocs: boolean

      check-ready-for-deposit:
        inputs:
          dbname: string
          includDocs: boolean

    actions:
      find-new-checks:
        inputs:
          CLOUDANT_USER: string
          CLOUDANT_PASS: string
          SWIFT_USER_ID: string
          SWIFT_PASSWORD: string
          SWIFT_PROJECT_ID: string
          SWIFT_REGION_NAME: string
          SWIFT_INCOMING_CONTAINER_NAME: string
          CURRENT_NAMESPACE: string

      save-check-images:
        inputs:
          CLOUDANT_USER: string
          CLOUDANT_PASS: string
          CLOUDANT_ARCHIVED_DATABASE: string
          CLOUDANT_AUDITED_DATABASE: string
          SWIFT_USER_ID: string
          SWIFT_PASSWORD: string
          SWIFT_PROJECT_ID: string
          SWIFT_REGION_NAME: string
          SWIFT_INCOMING_CONTAINER_NAME: string

      parse-check-data:
        inputs:
          CLOUDANT_USER: string
          CLOUDANT_PASS: string
          CLOUDANT_AUDITED_DATABASE: string
          CLOUDANT_PARSED_DATABASE: string
```

```
            CURRENT_NAMESPACE: string

      record-check-deposit:
        inputs:
          CLOUDANT_USER: string
          CLOUDANT_PASS: string
          CLOUDANT_PARSED_DATABASE: string
          CLOUDANT_PROCESSED_DATABASE: string
          CURRENT_NAMESPACE: string
          SENDGRID_API_KEY: string
          SENDGRID_FROM_ADDRESS: string

      parse-check-with-ocr:
        inputs:
          CLOUDANT_USER: string
          CLOUDANT_PASS: string
          CLOUDANT_AUDITED_DATABASE: string
          id: string
        outputs:
          result: JSON

    rules:
      fetch-checks:
        trigger:
          poll-for-incoming-checks
        action:
          find-new-checks
      scan-checks:
        trigger:
          check-ready-to-scan
        action:
          parse-check-data
      deposit-checks:
        trigger:

Event Sources

OpenWhisk is designed to work with any Event Source, either directly via published APIs from the Event Source's service or indirectly through Feed services that act as an Event Source on behalf of a service. This section documents some of these Event Sources and/or Feeds using this specification's schema.

Curated Feeds

The following Feeds are supported by the OpenWhisk platform within the IBM Bluemix Cloud platform. The are referenced by the term "curated" since they are maintained alongside the OpenWhisk open source code to guarantee compatibility. More information on curated feeds can be found here: https://github.com/openwhisk/openwhisk/blob/master/docs/catalog.md.

Alarms

The `/whisk.system/alarms` package can be used to fire a trigger at a specified frequency. This is useful for setting up recurring jobs or tasks, such as invoking a system backup action every hour.

Package Manifest

The "alarms" Package Manifest would appear as follows:

```
# shared system package providing the alarms feed action
alarms:
  version: 1.0
  license: Apache-2
  description: Alarms and periodic utility

  actions:
    alarm:
      function: action/alarm.js
      description: Fire trigger when alarm occurs
      feed: true
      inputs:
        package_endpoint:
          type: string
          description: The alarm provider endpoint with port
        cron:
          type: string
          description: UNIX crontab syntax for firing trigger in
Coordinated Universal Time (UTC).
          required: true
        trigger_payload:
          type: object
          description: The payload to pass to the Trigger, varies
          required: false
        maxTriggers:
          type: integer
          default: 1000
          required: false
```

```
feeds:
  location: TBD
  credential: TBD
  operations:
    CREATE:
      TBD
    DELETE:
      TBD
  action: alarm
```

760

Cloudant

762 The `/whisk.system/cloudant` package enables you to work with a Cloudant database. It
763 includes the following actions and feeds.

Package Manifest

765 The "cloudant" Package Manifest would appear as follows:

TBD

Public Sources

767 The following examples are Event Sources that can provide event data to OpenWhisk. We
768 describe them here using this specification's schema.

GitHub WebHook

770 Note: the GitHub WebHook is documented here: https://developer.github.com/webhooks/.
771

772 A sample description of the GitHub Event Source and its "create hook" API would appear as follows:

TBD

773

Other Considerations

Tooling interaction

Using package manifest directly from GitHub

GitHub is an acknowledged as a popular repository for open source projects which may include OpenWhisk Packages along with code for Actions and Feeds. It is easily envisioned that the Package Manifest will commonly reference GitHub as a source for these artifacts; this specification will consider Github as being covered by the general Catalog use case.

Using package manifest in archive (e.g., ZIP) file

Compressed packaging, including popular ZIP tools, is a common occurrence for popular distribution of code which we envision will work well with OpenWhisk Packages; however, at this time, there is no formal description of its use or interaction. We leave this for future consideration.

Simplification of WebHook Integration

Using RESTify

One possible instance of a lightweight framework to build REST APIs in Nodejs to export WebHook functionality. See https://www.npmjs.com/package/restify
RESTify (over Express) provides help in the areas of versioning, error handling (retry, abort) and content-negotiation. It also provides built in DTrace probes that identify application performance problems.

Enablement of Debugging for DevOps

Isolating and debugging "bad" Actions using (local) Docker

Simulate Inputs at time of an Action failure/error condition, isolate it and run it in a "debug" mode.

Considerations include, but are not limited to:

- Isolation on separate "debug" container
- Recreates "inputs" at time of failure
- Possibly recreates message queue state
- Provides additional stacktrace output
- Provides means to enable "debug" trace output
- Connectivity to "other" debug tooling

Using software debugging (LLDB) frameworks

This is a topic for future use cases and integrations. Specifically, working with LLDB frameworks will be considered. See http://lldb.llvm.org/.
